6 Abstract

7 Human verbal thinking is an object of many multidisciplinary studies. Verbal cognition is
8 often an integration of complex mental activities, such as neuro-cognitive and psychological
9 processes. In neuro-cognitive study of language, neural architecture and neuropsychological
10 mechanism of verbal cognition are basis of a vector -based modeling. Human mental states, as
11 constituents of mental continuum, represent an infinite set of meanings. Number of meanings
12 is not limited, but numbers of words and rules that are used for building complex verbal
13 structures are limited. Verbal perception and interpretation of the multiple meanings and
14 propositions in mental continuum can be modeled by applying tensor methods. A comparison
15 of human mental space to a vector space is an effective way of analyzing of human semantic
16 vocabulary, mental representations and rules of clustering and mapping. As such, Euclidean
17 and non-Euclidean spaces can be applied for a description of human semantic vocabulary and
18 high order. Additionally, changes in semantics and structures can be analyzed in 3D and other
19 dimensional spaces.

22 tensor model, dot and cross product, eigen space and ei

23 Vector-Based Approach to Verbal Cognition Chuluundorj B Abstract-Human verbal thinking is an object
24 of many multidisciplinary studies. Verbal cognition is often an integration of complex mental activities, such
25 as neurocognitive and psychological processes. In neuro-cognitive study of language, neural architecture and
26 neuropsychological mechanism of verbal cognition are basis of a vector -based modeling.

27 Human mental states, as constituents of mental continuum, represent an infinite set of meanings. Number of
28 meanings is not limited, but numbers of words and rules that are used for building complex verbal structures are
29 limited. Verbal perception and interpretation of the multiple meanings and propositions in mental continuum
30 can be modeled by applying tensor methods.

31 A comparison of human mental space to a vector space is an effective way of analyzing of human semantic
32 vocabulary, mental representations and rules of clustering and mapping. As such, Euclidean and non-Euclidean
33 spaces can be applied for a description of human semantic vocabulary and high order. Additionally, changes in
34 semantics and structures can be analyzed in 3D and other dimensional spaces.

35 It is suggested that different forms of verbal representation should be analyzed in a light of vector (tensor)
36 transformations. Vector dot and cross product, covariance and contra variance have been applied to analysis
37 of semantic transformations and pragmatic change in high order syntax structures. These ideas are supported
38 by empirical data from typologically different languages such as Mongolian, English and Russian. Moreover,
39 the author argues that the vectorbased approach to cognitive linguistics offers new opportunities to develop an
40 alternative version of quantitative semantics and, thus, to extend theory of Universal grammar in new dimensions.

41 1 Introduction

42 multidisciplinary approach to a study of human verbal thinking considered the human mental space as an infinite
43 mental continuum. Notions of Continuum (Cantor) and cardinality of sets are basis for measuring a mental

4 FIGURE 1

44 lexicon, capacity of semantic memory and mechanism of human verbal mapping. Therefore, mental spaces must
45 be presented as Euclidean and non-Euclidean spaces. Hilbert space generalizes the notion of Euclidean space and
46 extends the methods of vector algebra from the two-dimensional Euclidean plane and three-dimensional space to
47 spaces with any finite or infinite number of dimensions.

48 Semantic and pragmatic forces as constituents of human mental spaces present objects of modeling in terms of
49 vector (tensor) space. As such, these mantic space, as a kind of human mental space, must be presented as vector
50 space and semantic field -as a vector field. Language comprehension is symbolic through interdependencies of
51 modal linguistic symbols embodied through references. Grammar is an emergent product of distributed auto-
52 associator and pattern associator networks. In auto-associator network, all neurons are both input and output
53 neurons. This is one of the reasons to apply vector (tensor) space theory to an analysis of mechanism of embedding
54 input signals and organization of knowledge about the human mental space.

55 According to researchers of Max Planch Institute, semantic network can be treated as having directed and
56 undirected links (Ana, S. M., Henrik, O., & Lael, J.S. CS. 2013. 37/1 P 129). It means that semantic sets as a
57 fuzzy sets with links between nodes are the constituents of vector (tensor) space.

58 2 II.

59 3 Vector Representation of Word Meanings

60 Spatio-temporal patterns of human mental lexicon, semantic vocabulary are the specific object to apply vector
61 (scalar) method.

62 Human verbal perception of an object depends on particular coordinatization systems, of its intrinsic and
63 extrinsic features. Intrinsic features of space-time (curvature, metric tensor) are objectively real. Artifacts
64 of subjective coordinatization, particularly of verbal thinking spaces are extrinsic features. Embedding in
65 neural associative sets has reflected combination of intrinsic and extrinsic features that caused semantic changes,
66 transformations, and pragmatic interpretations.

67 According to researchers, the probability that a word and an object are paired is inversely proportional: the
68 strength of the associations between that word and all other objects present on that trial (A-b, A-c, A-d); the
69 strength of the associations between that object and all of the other words present within the trial (B-a, C-a,
70 D-a) (D. Yurovski., C. Yu., & L. B. Smith. CS. 2013. 37/5 P 912).

71 The words in associative sets have values and links (directions), which mean that the associative sets of
72 semantic vocabulary are an object of modeling in vector space. While concrete words can be represented within
73 a single neural network, abstract words can be appointed to a substantial degree of links between representations
74 in different neural networks (working associations). Concrete words share features ("taxonomic similarity"),
75 whereas abstract words share contextual association. An experiment on associative semantics in Mongolian
76 language illustrates the fact that concrete and abstract words differ in their association structure (Cognition and
77 Information. University of the Humanities. 2002. UB. P 8).

78 Super-distributed representations serve to incorporate two or more noun concept representations, ad hoc
79 creation of a contextual association. According to the experiment conducted at the University of the Humanities,
80 association structure of abstract words in verbal cognition of children served as one of the markers of their
81 cognitive development. Experiments on Mongolian language with participants, aged 3-4, have shown that verbs
82 are strongly dependent on their contextual associations. Sharing of contextual associations is closely connected
83 to generalization of words in semantic and pragmatic networks in clued take off a candy" -instead of "to unpack
84 a candy", etc.).

85 Thus, abstract verbs are more dependent on ability to maintain the associations in analogy to abstract nouns.

86 Introducing scalar field to analysis of localization and interconnection between words of different classes (sets)
87 in human semantic vocabulary has methodological significance.

88 Scalar-based modeling of human mental lexicon was shown by experiments on measurement of semantic spaces
89 between words, conducted in psycholinguistics laboratory of the University of the Humanities (IJALEL. 2013.
90 2/4 P 192). Moreover, vector dot product is $(a \cdot b = |a||b|\cos\theta)$ a powerful tool for modeling localization
91 of different classes of words in human mental space and connections of these classes with different regions of
92 the brain. A similarity in the distance between word groups can be measured by applying law of cosines and
93 law of sines to vector product. A good illustration of this is experiments on associative links between words
94 ("????????, ??????"?) in children's memory. For example: "Please, take a play from the bed (go to the
95 sofa)." "Please, wash the elbow (knee)."

96 Upon a stimulation, such as parent's request, children use relevant for them associative links, and a distance
97 between these "associated" words must be measured by using law of cosines: $\cos\theta = \frac{a \cdot b}{|a||b|}$.
98 Stimuli (verbs) are a starting point for measuring a similarity (or a magnitude of associative relations) between
99 words at the time of their response.

100 4 Figure 1

101 Similarity between these words is an effect of generalization principle in child semantic lexicon. That is why a
102 use of law of sines as an addition is important in finding the direction of associative relations between words.

103 Therefore, an application of the law of cosines and law of sines to human semantic vocabulary is efficient for
104 understanding of universal principles of mental lexicon.

105 A relation between the size of a whole and the size of parts in language and music follows the Menzerath-
106 Altmann law: the larger a whole, the smaller its parts. In language area it is described as "the longer a word (in
107 syllables), the shorter its syllables (in letters or phonemes)" (Jaume, B., Antoni, H. F., Luria, F., & Ramon, F.
108 C. JQL. 2013. 20/2 P 95).

109 An applicability of this law to typologically different languages, such as Mongolian, Chinese, English and
110 Russian), is important in linguistics.

111 Human semantic memory has strong effect on spatial perception. Chinese language is a specific case for such
112 perception. RH lateralization of Chinese character processing has left an advantage of a visual field (LVF)/RH.
113 This lateralization difference between Chinese single character and two-character word processing means that
114 reading of the two-character words requires a decomposition of the words into their constituent characters and,
115 thus, involves more HSF (high spatial frequency)/LH processing (Jamet, H. H., & Sze, M. L. CS. 2013. 37/5.
116 P 880).

117 Additionally, the idea of lateralization difference can also be used in comparison of traditional Mongolian and
118 Cyrillic scripts. Horizontal and vertical writing in scripts is a phenomenon and, thus, a matter of description in
119 terms of spatial and verbal cognition.

120 Therefore, two models of mathematical cognition, such as segmented linear model and loglinear model, are
121 interesting methods to organize semantic memory (David, L., & Noach, S. CS. 2013. 37/5 P 778).

122 An association between color perception and mathematical cognition is directly related to verbal thinking.

123 For some people, numbers have colors (Stanislas Dehaene. Numerical cognition. 1993. Oxford. P 75) and a
124 human ability to communicate is a basis for such kind of multi-modal integration that underpins mental, semantic
125 lexicon. This idea also refers to high order verbal structures.

126 5 III.

127 6 Vector -Based Analysis of Syntactic Structures

128 Syntax is a highly distributed language process, which sharply contradict shyper localized function. Syntactic
129 structures must be presented in conceptual spaces and vector field, and they are used to describe as emantic
130 potential with pragmatic (illocutive) force. However, mapping of events and objects in the brain (verbal mapping)
131 is different. As such, primitives of mental mapping is a product of primes, whereas proposition and concept -
132 are the products of a unit. Also, an integration of discrete structural elements (words or musical tones) into
133 sequence-perceiving complex acoustic, non-verbal or mathematical structures (symbol) is a product of blending.
134 This has been demonstrated in experiments on metrical stimuli for analysis of musical, numerical and syntactic
135 structures. In these experiments, primary colors are associated with small numbers and more complex colors
136 are associated with larger numbers. Basic metaphor of these arithmeticis an intuitive notion of divisibility and
137 decomposition of an integer into product of primes.

138 In numerical grammar, some words combine additively -forty-three (40+3), whereas others combine multi-
139 plicatively: seven hundred (7x100) (David, L., Noach, S., & Aleah, C. CS. 2013. 37/15 P 793). This number
140 processing is similar to syntactic processing. For example:

141 A concept of perfect numbers in combination with prime numbers is also useful for description of deep
142 structures, particularly proposition-based structures. Finally, syntactic priming is a reflection of an implicit
143 statistical knowledge that is relevant to language processing, and the principle of sequence regularities is expressed
144 in simple recurrent networks.

145 7 Analysis of word sequences: adjective-noun

146 In expressions containing attributive, causative, space-time and other relational properties, order regularities
147 reflect the properties of specific regions of the brain. This suggests that some overlap between the cortical areas
148 coding for numbers, space and colors may remain ??Stanislas, D. 1997.P 38).

149 Color may be a more consistent feature of the typical evocation of a given distributed visual representation
150 than size. Semantic relationships between nouns, verbs, and adjectives are a reflection of knowledge sequence
151 represented in prefrontal association cortex and its connections, phrase structure rules and grammatical
152 morphology sequence knowledge-in perisylvian pattern associator networks.

153 According to the researchers, structures book) in semantic compositions, are based on human similarity
154 judgments (Jeff Mitchell., & Mirella Laputa.2008. Vector-based models of semantic composition... Edinburgh,
155 UK.) Adjective order (e.g., value, size, color) is substantially consistent across a large number of languages. In
156 some adjective structures (?"@????@?, ???, ???????; ???"@????@????, ???, ???), semantic force presents object-
157 oriented vector. For example:

158 Figure 2

159 Such structures are interpreted in tensor space with syntactic reduction nn L with vectors N?N (Edward
160 Grefensette., & Mehrnoosh Sadrzadeh? 2010.) In Mongolian language, distributional function is also applied

12 ACTION/EVENT AS AN OBJECT OF ANALYSIS IN VECTOR (TENSOR) SPACE

161 to an analysis of attributive structures as linear transformation in tensor (vector) space. If noun (?????) is
162 represented as vector, adjectives are determined by distributional behavior of the noun.

163 8 Figure 3:

164 Typical features of an object (size, color etc.) in human perceptual space (topological tensor space) area basis
165 for a calculation of cue validity: $c x (A) = P(x|A)$. The question is: how typical?? 1 , ?? 2 ??????? ?? 3 values for
166 Aare related to the features (adjectives??????, ??, ?????) of the object (??????) in case of ?? 1 , ?? 2 ??????? ??
167 3. Complex expression with two or more adjectives must lead to superposition of instances. Superposition of
168 complex adjectival expressionist is a case of semantic interference where a trace of 2 nd rank tensor is implied.

169 9 Figure 4

170 According to psycholinguistic experiments, color affected shape recognition as an intrinsic feature of the shape.
171 Mechanism of binding of intrinsic and extrinsic features in working memory, for example, binding of color and
172 shape, determined similarity and difference in verbal perception of people.

173 Vector-based analysis of sequence regularities in above named structures proposes that implicit statistical
174 knowledge in working memory reflects the relevance of intrinsic and extrinsic features of an object to verbal
175 cognition.

176 10 Analysis of word sequences: Verb-noun aspect of polysemy

177 In multi-word expressions, complex effect of semantic and pragmatic forces raises an issue of linearity and non-
178 linearity: In the experiments conducted by Mongolian researchers, a correlation of the predicate and arguments
179 (or object) differs from verbs (predicate) that have similar meanings and nouns (argument or object) of the same
180 semantic group.???(book)-distance

181 11 Figure 5

182 The perception tests of "noun-verb"? in Mongolian language showed different levels of interpretation for children
183 and adults:

184 to take table (children) to make a career (adults) A computing of a similarity or difference between the vectors
185 of a predicate and arguments (object) is not an ending point. Applying vector cross product is one way to analyze
186 complex effect of semantic and pragmatic forces on semantic transformations in different directions. Pragmatic
187 force F is applied to an "illocutive key" (a displacement r) from a specific point of rotation. The question is:
188 which part of F causes the "illocutive key" to turn?

189 In some situations, pragmatic force can support intention flow which is perpendicular to a plane containing
190 both vectors. Semantic/pragmatic pressure on word in different directions causes semantic cohesion and coherence
191 what presents a case of entanglement as a result of non-linear combination of semantic and pragmatic forces. In
192 terms of quantum coherence however, a moment of synthesis of semantic and pragmatic meanings is two forces
193 having the same carriers. The carriers of these meanings at neuropsychological level are significant "particles"
194 for verbal perception and present an object of interpretation in terms of tensors of ranks 2 and 3. It means that
195 dyad and triad tensors are effective for modeling of cohesion and coherence of semantic and pragmatic forces in
196 syntactic structures.

197 12 Action/event as an object of analysis in vector (tensor) space

198 Semantic "energy" distribution throughout mental (semantic) space in verbal mapping of action/event structure
199 must be analyzed in scalar modeling and differential geometry. Event and action present basic primitives for
200 mental syntax. In working memory, events are organized into hypothesized sequences of more general states
201 (actions in a process of making coffee), encoded in a set of neural units expressing features or states. Sequences
202 of these states can be referred to higher level sequences which form multi-level hierarchy (Marten, S., Andy, E.,
203 & William, S. Topics in CS. 2013. 5/3. P52).

204 Neuropsychological analysis of sentence structures suggested that verbs have a distributed representation
205 of prefrontal components with thematic attribute, argument structure and sub categorization in sentence-level
206 sequence; posterior components which support flavor attributes and implementational components of premotor
207 and motor cortex. This is related to specific mechanism that generates syntax structures from basic primitives
208 (Vlasova, P., Pechenkova, E. B., Akhutina, T. B., & Sinitin, B. E. 2012. ?? 4/129). Moreover, goal-directed
209 sequential concept manipulation is based on distributed semantic representations, phonologic and morphologic
210 sequence knowledge and sentence-level sequence knowledge. In typologically different languages (like Mongolian,
211 English and Russian), differences in sentence structure are particularly reflected in commutative and associative
212 properties of vector addition. For example: $U + V = V + U$ (commutative property) $U + (V + W) = (U + V)$
213 $+W$ (associative property) SOV S + (O + V) SVO S + (V + O)

214 The boy caught the ball.

215 Vector dot product that describes sentence structures can be used in relevance to component analysis of such
216 structures.

217 13 Figure 7

218 Semantic force (of a word, sentence etc.) changes distance of the word (strong or weak link, but no direction).
219 Also, as a vector, semantic force has magnitude and direction (?) that change semantic volume (density or
220 distance) of the word. In the first case, semantic force behaves as a scalar, in the second case -as a vector.

221 At sentence level for connection of words, denotative and connotative components of word semantic structure
222 drive interaction. This interaction is affected by a semantic force in one direction, by a pragmatic force
223 or a combination of semantic and pragmatic forces -in the other directions. However, it is not clear how
224 isomorphism/homomorphism can be related to interpretation of SOV and SVO.

225 It is known that tensor products of A and B over R module ?AxR ? A?B are important in interpretation
226 of existence of bilinear homomorphism in typologically different languages. In this connection, a compositional
227 distributional analysis provides a way to interpret sentence structures in tensor (vector) spaces (Grefenstette,
228 E., Pulman, S., Sadrzadeh, M. & Coecke, B. (1998). Concrete sentence space for compositional distributional
229 models of meaning). In tensor spaces, the syntax relations, including distributional meanings of verbs as weighted
230 relation, are represented by linear maps. For example:

231 The boy caught the ball (S-V-O)(S-O-V) (S-V-O) ??????? = ?(?????? ?? ??????? ? ?????? ?? ???????)
232 ??

233 The verb in this context is created by context vectors of the subject and object.

234 In typologically different languages, such as English, Russian (SVO) and Mongolian (SOV), the con-
235 text vectors of subject and object can be calculated in two different ways:?????? ??????? ???????
236 ????????????????????????? = ?????? ?????? ? (????????? ?????????? x ?????? ??????) ???????
237 ?????? ?????? ????????????????????????? = ?????? ? (?????? ??????? x ??????? ??????????)

238 SVO structure in tensor space N?S?N corresponds to the type n R sn L (n R -right adjoint, n L -left adjoint).
239 For example:

240 They ate the meat. The man opened the letter.

241 In syntax of the typologically different languages, implicit statistical analysing of working memory can be used
242 in relation to language processing: John gave his daughter a book-John gave a book to his daughter.

243 The girl threw the ball to the boy -The girl caught the ball from the boy.

244 Parallels in Russian and Mongolian languages:

245 These structures support the idea of tectonics of syntax structures that reflect tectonics of actions. This
246 is in agreement with a concept, which suggests that a reciprocal manipulation of two or more distributed
247 representations is particularly determined by a neural instantiation of the association of a verb with a specific
248 argument structure. The simplest method to calculate the number of vectors acting in different directions is
249 vector addition. Applicability of rectangular component method to interpretation of such structures is an issue
250 having methodological?

251 Vectors presenting object components have different magnitude of direction of subject and predicative
252 component (action verb). Moreover, Attributive relations and different features of manner are objects of
253 description in Cartesian coordinates by using resultant vector. For example: She has been taking new efficient
254 medicine.

255 14 Figure 8

256 In addition, use of resultant vector in analysis of multi component structures is an effective addition to traditional
257 interpretation of manner of action. For example:

258 The boy with his brother moved the table.

259 The boy with his younger brother moved the table. The boy heard the door slamming all night long.

260 In manner incorporating languages (English, Russian and Chinese), manner representation is closely connected
261 to intrinsic movement and movement in peri personal space. However, in path incorporating languages (Japanese
262 and Turkish), path incorporation is represented posteriorly, in cortices supporting the spatial location components
263 (Stephen, E.N. 2012. The neural architecture of grammar. P42.). Interestingly, "manner-action" structures are
264 also connected in different ways and those illustrate the universality of addition and multiplication operations
265 for mathematical and verbal reasoning. ?????????? ?????????? ?? ?????? ??????. ??????, ?????????? ?? ? ??????.

266 ?????? ??????? ?????? ?????????? ????.

267 ??? ??????? ????"?"?"?"?"

268 ??? ??????? ????"?"?"?"

269 different ways depending on typology of language. Also, use of associative law (A ? ?? +(B ? ?? + C ??) =
270 (A ? ?? + B ? ??) + ?? ?) is effective for structures with two or more components which express manner or
271 path. Complex vector can be applied to these multi component structures.

272 15 Schema-based transformations

273 Rules for mental transformations, based on rules (mechanisms) of perceptual spaces (modalities), are a basis
274 for semantic transformations (clustering, embedding and multidimensional mapping). Cross modal organizational
275 structures (COGs), supported by mirror neurons and corresponding image-schemas (container schema, source-
276 path-goal schema, spatial relation schema, complex relations schema), are common in most languages. At deep

17 COMPLEX STRUCTURES

277 level these imageschemas serve as a basis for semantic transformations: He goes through the doorway -The room
278 is through the doorway.

279 He went through the forest -The road goes through the forest.

280 Among them, the source-path-goal schema has an internal spatial "logic" and built-in inference which are
281 also stimulated semantic transformations. Differently, applying of vector method to force-dynamicschema that
282 generates passive structures leads to deeper analysis of neuro-cognitive mechanism for producing human mental
283 transformations. Moreover, active and passive structures (Many critics disliked the play? The play was disliked
284 by many critics) are an object to interpretation in terms of vector/matrix transformations as structures involving
285 two vectors. Formally, it is not a simple conversion.

286 16 Figure 9

287 There is a change in a vector direction that is reflected in distance between components of sentence. Model of
288 an event can have a complex structure and involve two vectors (agent and patient), counterforce and instrument.
289 For example:

290 The window was broken by the boy.

291 The boy has broken the window. The boy has broken the window by throwing a stone.

292 A vector-based description of passive structures without agents, for example" is significant in relation to
293 isomor-phism/ homomorphism.

294 In visual perception, a transformation from egocentric frames of reference with respect to body (self-to-object
295 relations) to all ocentric frames of reference with respect to external objects (object-toobject relations) is related
296 to a transformation from active structures to passive ones (Wen, W., Toru, I., & Takao, S. 2013. CS. 37/1. P
297 177). There is also a possibility for an implication of stress tensor ($?=F/A$) to interpretation of difference in
298 active and passive structures.

299 Space-time dimensions of verbal perception have a marked representational granularity causing difference in
300 event focusing. For example:

301 There is a table. In locative constructions, verb slot in the ground (or container) is associated with the semantic
302 property of manner of motion (for ex., Lisa poured water into the cup)or with the semantic property of state-
303 change (for ex., Lisa filled the cup with water).Thus, generalization leads to semantic change and transformations,
304 such as motion ? state: Form the other side, state of subject can be transformed into a localization state (for ex.,
305 Vector-based analysis of dependency of verbal perception on coordinatization showed that semantic structures
306 derive from deep mental structures. Semantic derivatives are important elements of semantic transformations. For
307 example, markers for temporal relations originate from spatial expressions, which are products of human mental
308 perception of complicated space -time relationships. In human verbal perception, the above named structures
309 have eigen value for a vector under transformation.

310 Highly differentiated active and passive structures are an object of analysis of covariance and contra variance.
311 Covariance and contra variance, as results of sensorimotor embedding, serve as vectorial expressions in the human
312 motor frame. However, covariance and contra variance of vectors are different basic descriptions of the same object
313 indifferent referential frames.

314 17 Complex structures

315 Complex structures in typologically different languages are an object to tests of memory-based accounts of
316 syntactic complexity. In Mongolian language, dependency between encountered component (V-?????) and
317 memory-retrieved component(S, O) is flexible. For example: Subject-orobject-extracted conditions can be
318 determined by cohesion. In complex sentence, element formation is highly active in memory at the point of
319 the dependency. For example:

320 It was John who consulted Ellen in the library.

321 It was Ellen who John consulted in the library.

322 When second element of dependency (consulted) is encountered, the object "Ellen, Ph.D. student" is retrieved
323 from memory (Evelina, F., Rebecca, W., & Edward, G. CS. 37/2 P 387).

324 In complex structures, a component expressing particular relation must consist of two or three subcomponents
325 (words) and, in this case, such structures must be presented in a complex vector model. An example is so-called
326 "recursion" which is a process of inserting successive nested relative clauses into sentences and the realization of
327 three or more different concept representations at the same time. For example:

328 The woman, whose husband was fishing for great white shark, sat down beside me.

329 The woman whose dress rustled when she walked sat down beside me.

330 For description of complex sentences, it is necessary to take into consideration that motion paths can
331 intrinsically be divided into parts that belong to a single event. It means that there is a positive multiple of
332 an event inthe human mental syntax motion vector (the derivative). Thus, a vector-based analysis of recursion,
333 supported in the brain by a pushdown memory mechanism as a mirror recursion, suggests that the concept of
334 complex structures is revised in dynamic dimensions.

335 Complex sentences have complex values as a common effect of two types of fields (or forces): semantic and

336 pragmatic. Force density must be presented by a tensor, its stress function. This is one of the reasons to apply
337 complex vector to these structures, and to develop unified field theory in cognitive linguistics.

338 IV.

339 18 Discussion & Conclusion

340 In the recent paper we presented vector-based approach to human verbal cognition by providing a description of
341 word meaning and syntactic structures. Human mental space is the basis for an application of vector (tensor)
342 method to modeling of human verbal perception and mental representations.

343 Vector dot product is a powerful tool for modeling of localization of different classes of words in semantic
344 memory, and connections of these classes with different regions of the brain. This idea is illustrated by means of
345 examples in English, Russian and Mongolian languages and by result of experiments conducted at the University
346 of the Humanities. The author suggests that application of the law of cosines and the law of sines to the modeling
347 human semantic lexicon is an important addition to the vector method. Thus, interpretation of word sequences in
348 vector space is an effective way for analysis of basic rules which regulate these sequences in typologically different
349 languages.

350 A concept of cue validity and superposition is used for modeling of feature-based perception of an object and
351 its properties. It is important to establish linear or non-linear correlation captured by cue validity in studies of
352 human mental clustering. Furthermore, a superposition principle can be applied to the analysis of interference
353 of components expressing different features of an object and action in syntactic structure.

354 A 2 nd rank tensor can be implied to the analysis of non-linearity in word sequences, and this presents interest
355 in terms of dependency of verbal cognition on typology of language. In particular, the tensor-based analysis of
356 sentence structures supports the idea that tectonics of syntax structures reflect tectonics of action/event. Also,
357 use of vector cross product for an interpretation of semantic and pragmatic forces at a sentence level allows a
358 deeper analysis of neurocognitive mechanism behind mental transformations. This idea is supported by number
359 of examples in English, Russian and Mongolian languages.

360 Experiments, conducted at the University of the Humanities, demonstrated that representational granularity
361 in mental mapping leads to typological differences in languages. Additionally, tensor-based analysis of verbal
362 perception on coordinatization showed that semantic structures are derivatives of variance present vectorial
363 expression in human motor frame as a result of sensorimotor embedding.

364 Finally, an application of vector (tensor) method to human mental syntax may result in high order verbal
structures and provide a new opportunity to develop unified field theory in cognitive linguistics.
