Application of Geographic Information System To The Effects of Climatic Variability on Sustainable Agricultural Production in Kwara State of Nigeria Dr. H.I Jimo¹ ¹ Univervity of Ilorin, Nigeria Received: 22 June 2011 Accepted: 18 July 2011 Published: 28 July 2011

8 Abstract

This research endeavour is on the application of Geographic Information System (GIS) as a 9 tool for analysing the roles of microclimatological characteristics of the study area on the 10 production rates of some selected agricultural products. In the process, specific climatic 11 parameters were used so as to observe the climatic trends over a decade with that of 12 agricultural production rates. Essentially, the required datasets were sourced from the 13 Nigerian Meteorological Agency, Kwara Agricultural Development Project Office and Survey 14 Department of Kwara State Ministry of Lands and Housing, Ilorin. The climatic data were 15 later analysed through condescriptive statistical techniques and the use of charts to show the 16 rates of variation among the parameters used. Also, the selected crops were shown on charts 17 too so as to reveal the trends of variation between the rates of crop production too. Finally, 18 the climatic data were drawn against the crop production rates to indicate concisely the 19 trends of climatic variation especially as it affects the crop production rates over the decade. 20 Essentially, the following constitute as the major observations from the analysis of the datsets: 21 First, most of the crops had the highest yield for the decade in 2008. And in year 2001 the 22 highest value of temperature was recorded while relative humidity and rainfall had second to 23 the lowest values. Further, Year 2004 had the highest rainfall value, temperature and relative 24 humidity were moderate where maize, cassava and rice recorded below average yields. Then, 25 sorghum had its second to the lowest yield value. In essence, the climatic parameters have 26 been found to play crucial roles in the productivity rates for all the crops tested or 27 investigated, meaning that clear understanding about the relevancies of these climatic 28 parameters should be understood before engaging in agricultural activities so as to avert the 29 incidence of crop failures. 30

over a decade with that of agricultural production rates. Essentially, the required datasets were sourced from 40 the Nigerian Meteorological Agency, Kwara Agricultural Development Project Office and Survey Department of 41 Kwara State Ministry of Lands and Housing, Ilorin. The climatic data were later analysed through condesctriptive 42 43 statistical techniques and the use of charts to show the rates of variation among the parameters used. Also, the selected crops were shown on charts too so as to reveal the trends of variation between the rates of crop production 44 too. Finally, the climatic data were drawn against the crop production rates to indicate concisely the trends of 45 climatic variation especially as it affects the crop production rates over the decade. Essentially, the following 46 constitute as the major observations from the analysis of the datsets: First, most of the crops had the highest yield 47 for the decade in 2008. And in year 2001 the highest value of temperature was recorded while relative humidity 48 and rainfall had second to the lowest values. Further, Year 2004 had the highest rainfall value, temperature and 49 relative humidity were moderate where maize, cassava and rice recorded below average yields. Then, sorghum 50 had its second to the lowest yield value. In essence, the climatic parameters have been found to play crucial 51 roles in the productivity rates for all the crops tested or investigated, meaning that clear understanding about 52 the relevancies of these climatic parameters should be understood before engaging in agricultural activities so as 53 to avert the incidence of crop failures. 54

55 Keywords : Applications, GIS, Effects, Climatic Variability, Agricultural Production, Kwara State, Nigeria.

56 limate variability is rapidly becoming the most important environmental challenge facing mankind. Small 57 temperature changes may seem inconsequential to the unwary, but only because small temperature shifts are 58 often inconspicuous to people. A small temperature change to the vast volume of oceans covering the earth represents immense changes in the energy system. These energy changes can become concentrated and focused, 59 resulting in massive hurricanes and storms. The slightest temperature change at the right moment can trigger 60 outbreaks of insect pests or disease vectors, which can destroy entire landscapes, forest or croplands. Everything 61 in nature is related, so outbreaks or changes in one area trigger changes in other areas. For example; the 62 immediate survival of many coastal areas, populations, forests and wildlife may now depend on our ability to 63 study, understand and share the small changes we observe in the environments and ecosystems around man. 64

The current talk about climatic variability has been correlated with the activities of man which have in turn generated microclimate variations, pollution of environment by forest fuels burnt daily from industries and automobiles all of which generate heat, there by altering the heat balance. Specifically, urbanization has been found to modify the city climate ??Bryson and Ross, 1972). And this include the effects of the changes in physical land surface, which increases in roughness and wind speed. Further, several human activities generate enormous particles into space that are capable of greatly modifying the solar energy incident on the earth surface ??Landsberg 1970).

Abnormal changes in temperature and rainfall, increasing frequency, intensity of droughts and floods have 72 long-time implications for the viability and productivity of world agro-systems. Essentially, agriculture is the 73 sector most affected by changes in climate patterns and will be increasingly vulnerable in the future. Especially 74 at risk are developing countries, which are highly dependent on agriculture and have fewer resources and options 75 to combat damages from climatic variation. Agriculture is the production, processing, marketing and use of 76 foods and bye products from plants and animals. As a matter of fact, agriculture was the key development 77 that led to the rise of human civilization, with the husbandry of domesticated animals and plants (i.e crops) 78 creating food surplus that enabled the development of more densely populated and stratified societies. The 79 major agricultural products can be broadly grouped into foods, fibres, fuels and raw materials. Specifically, in 80 the 21 st century, plants have been used to grow biofuels, biopharmaceuticals, bioplastics etc. specific foods 81 include; cereals, vegetables, fruits and meat. Fibres include; cotton, wool, hemp, silk and flax. Raw materials 82 include; lumber and bamboo, other useful materials produced by plants are resins. Biofuels include; methane 83 from biomass, ethanol and biodiesel. Cut flowers, nursery plants, tropical fish and birds for the pet trade are 84 some of the ornamental products too. To appreciate the relevancies of GIS in all of these discussions, the basic 85 components of a GIS are the computer system, geospatial data and users. To this end, a GIS will permit the 86 performance of three fundamental stages of work namely; i. 87

Data Entry:-early stage in which data about the studied phenomena is entered into the GIS and representations are built. ii.

Data Analysis:-middle stage in which representations are manipulated and studied to gain (new) insight. iii.

Data presentation:-final stage in which the results of analysis are presented in maps or otherwise. 91 With GIS, we operate on and manipulate a representation of real world phenomena (model of it). Man has for 92 ages been interested in climate and the study of climate is as ancient as man's curiosity about his environment. 93 This is hardly surprising since climate influences man and his diverse activities in numerous ways. The air that 94 man breathes, the food he eats are weather related, even his occupation, clothing and forms of shelter are to a 95 large extent determined by the micro climatic condition of his area. Modern man not willing to live at the mercy 96 of weather like his primitive ancestors wants to study, understand, manage and even control weather especially 97 for his immediate locality in order to predict, modify or control it where possible. Some areas of man's life where 98 weather and climate is posing serious challenges is largely on agriculture. 99 The main focus of this work is to examine the climatic characteristics and the trends in relation to agricultural 100

I ne main focus of this work is to examine the climatic characteristics and the trends in relation to agricultural
 production. To achieve this, the following specific objectives are have being focused as follows: i.

102 To study and present some climatic parameters in relation to agricultural production,. ii.

To determine the trends of agricultural productivity over a decade; and iii. To forecast the possible climatic conditions as it may affect agricultural production.

The atmosphere is not static, rather it is in constant turmoil. Its characteristics change from place to place 105 and over time at any given place on time scales ranging from microseconds to hundreds of years. There are 106 important interactions within the atmosphere causing such changes. Thus, the changes within the atmosphere 107 may be internally induced within the earth atmosphere system of externally induced by extraterrestrial factors. 108 Essentially, weather variations and climatic variations. Weather is extremely variable particularly in the 109 temperate region. But whether in the tropics or in the temperate region the existence of diurnal and seasonal 110 weather changes cannot be denied. The weather changes collectively make up climate. There are variations in 111 climate itself. When these fluctuations follow a trend we talk of climatic trends. Over a long period of time, 112 climatic fluctuations may be such that, a shift in type of climate prevailing over a given area takes place. In that 113 case, we talk of a change in climate or climatic change. Importantly, the components of climate that seriously 114 influence agricultural productivity levels are temperature, humidity and rainfall, others are air pressure, sunshine 115 rate, cloudiness, nature of surfaces among others (see tables 1 and 2). As a matter of fact, the impact of climatic 116 variability on agriculture in most developing countries with crop failure and livestock deaths are causing higher 117 economic losses and thus contributing to higher food prices and under mining food security with great frequency. 118 119 Also, increasing population's demand for food is rising. Below are some of the areas of agriculture that has been 120 affected by climatic variability;

¹²¹ 2 b) Crops

122 The effects of increased temperature and CO 2 levels on arable crops will be broadly neutral;

123 **3**

124 The range of current crops will move northward. -New crop varieties may need to be selected.

125 4

Horticultural crops are more susceptible to changing conditions than arable crops. -Field vegetables will be particularly affected by temperature change. -Phaselous bean, onion and sweet corn are most likely to benefit commercially from higher temperature. -Water deficits will directly affect fruit and vegetable production.

¹²⁹ 5 c) Grass lands and Livestock

130 -There is unlikely to be a significant change in suitability of livestock in some systems.

131 6

132 Pigs and poultry could be exposed to higher incidence of heat stress, thus influencing productivity.

133 7

134 Increase in disease transmission by faster growth rates of pathogens in the environment and more efficient and 135 abundant vectors e.g insects.

136 8

137 Consequences for food quality and storage.

¹³⁸ 9 d) Weeds, Pests and Diseases

Weeds evolve rapidly to overcome control measures, short lived weeds and those that spread vegetatively (creeping,
buttercup, couch etc) evolve at the greatest rates; -Rates of evolution will increase in hotter, drier conditions and
in extreme years; could lead to some types of herbicide tolerance becoming more common.

-Possible increase in the range of many native pests and species that at present are not economically important
 may become so. -Surveillance and eradication processes for other significant pests such as the colarado beetle
 will become increasingly important.

Essentially, the output from a GIS in the form of maps combined with satellite imagery allow researchers to view the subject in an impressive way that are also invaluable for conveying the effects of climate change to nonscientists. Prediction of impact of the variation in climate on any area of interest, especially, agriculture inherently involves many uncertainties stemming from data and models. This of course is the place GIS application in this paper and have been in part documented in the work of De Smith Goodchild, (2008) 1).

The vegetation belongs to the Tropical Savannah which comprises dense forest population in most parts of the state and derived vegetation within and around the urban centres and characterized with scattered trees among grasses that grow high such as spear grass, elephant grass and goat weed while the trees include; Baobab, Acacia, Locust-beans Shea butter trees among others.

154 The weather type in the State belongs to the Humid tropical climate (see tables 3 and 4).

155 10 THE STUDY AREA

The monthly temperature values are in Jan 25.9 o c, June 26. The Tropical Maritime air mass from the Atlantic Ocean is prevalent from March to Oct, while the tropical Continental air mass from the Sahara desert takes over from Nov to Feb ??Olaniran, 2002). This results in two seasons; raining season (March-Oct) exhibiting double maxima rainfall pattern with peak periods in the months of June and Sept. it is succeeded by prolonged dry (harmattan) dry season between Nov-March. Humidity vary seasonally ranging from 75% to 80%.

162 11 MATERIALS AND METHODS OF STUDY

The study area (Kwara state) is made up of 16 Local Government Areas grouped into four (4) zones (see table 5). The data required for accomplishing the philosophy of this work have been drawn from: Primary source

(geo-spatial data and the attribute data of the study area to get a digital map of Kwara), and Secondary source(

the meteorological data for the climatic parameters that was obtained from the records of Nigerian Meteorological Agency), Ilorin International Airport, while information on the trends of agricultural production were collected

168 from the records of Kwara Agricultural Development Project, Ilorin.

169 12 DATA ANALYSIS AND DISCUSSION OF

170 13 RESULTS

171 Many issues of relevance are as considered for achieving the philosophy or the central tenets of this research 172 endeavour as follows.

a) The roles of climatic parameters on agricultural Generally, the comparison between the rates of variability in climatic conditions and the yield rates of the selected crops covering the years under study indicates the level of influence the climatic parameters have on the rates of cop yields between the periods under study.

In year 2001 the highest value of temperature was recorded (regarded as a hot year), relative humidity and 176 rainfall had second to the lowest values while cassava and maize recorded the lowest yield and the values for rice 177 and sorghum were below average. In 2003, lowest values were recorded for temperature and rainfall but relative 178 humidity had its second highest value, sorghum and rice also recorded their lowest yield while maize, cassava 179 and vam yield values were below average value. Year 2004 had highest rainfall thus can be regarded as a "wet 180 year", temperature and relative humidity were moderate where as maize, cassava and rice recorded below average 181 yields then sorghum had its second to the lowest yield value. 2008 recorded the highest yield value for most of 182 the crops except sorghum which was also above average yield, while relative humidity was highest, rainfall value 183

was above average and temperature had the exact average value.
In observing the trends of climatic variability and agricultural production as demonstrated earlier it becomes

obvious that the climatic variability has been for a very long time and is still in operation in the environment.
The challenges posed by climate may worsen if necessary checks are not taken and this will certainly affect
agricultural production as it may drop drastically in the next few years.

189 14 CONCLUSION

190 Strong relationship has been found to exists between agricultural production and climatic variability. The trend

in the climatic variables under study shows that the variability is felt where local factors of climate directly

affects agricultural production. For instance, many places still depend on rain-fed crop production system and

agricultural production rate is therefore easily affected by any slight adverse condition of weather. Thus, the use
 of GIS technology has greatly enhanced both the scope and quality of environmental management and planning,
 which has become more focused and goal oriented.
