8 **Abstract**

9 The study aimed to assess the effect of the flood on women farmers? activities in flood- prone
10 areas in Ibadan Metropolis, Oyo State, Nigeria. Sampling technique was multistage, data were
11 collected with the aid of a questionnaire using an interview format to eighty-one respondents.
12 Descriptive and inferential analyses were used to analyse the data obtained. The result
13 revealed that livestock production was the most engaging activities and findings showed that

17 **1 Introduction**

18 n the past, Agriculture was the most significant sector in Nigeria. The environment was so conducive to farming
19 and other related activities with the support of the government. Agricultural proceeds have been used to develop
20 the country since the independence. The agriculture sector was doomed in Nigeria in the year 1970, the end of
21 the Biafran war, which coincided with the rise in the world oil price. The country was able to benefit from the
22 boom, which made the government neglect the agricultural sector. According to the National Bureau of Statistics
23 (2012), the oil and gas industry have taken over the farming segment of Nigeria's economy as a result of the
24 world oil boom in the 70s.

25 Surprisingly a nation with over 70% of the population employed in agricultural sector is still playing second
26 fiddle to the oil and gas sector. It was so bad to the extent that that about 84 million hectares of Nigeria's total
27 land area, which has potential for agriculture, only about 40% of this is under cultivation ??FMARD, 2012).
28 Also, the few lands under cultivation are facing issues ranging from natural disasters to human afflicted problems,
29 thereby preventing the nation from achieving its full potential in the agricultural related activities. The vision of
30 Nigeria to be among the first top twenty nations in the agricultural production could be a mirage if agricultural
31 farmlands are not safe from the frequent occurrence of environmental disasters in the country.

32 Floods are major environmental disasters affecting agricultural activities in Nigeria. European Union (2007)
33 sees it as a covering of land by water that is not covered by water before the incidence. According to the United
34 Nations (UN) report of 1998, 23 million people were affected as a result of flooding in Xian, China (UNFCCC,
35 2007). Furthermore, severe floods also killed over two hundred people in India and Bangladesh and left millions
36 homeless (Erekpokeme, 2015). Odufewa et al. ??2012) report that floods are the most occurring, widespread,
37 disastrous and frequent natural hazards of the world.

38 It is on record that Ibadan the capital city of Oyo State Nigeria, has recorded varying degrees of flooding. For
39 instance, there were flooding in the watersheds of Ogunpa and Kudeti streams (one of the two major streams in
40 Ibadan) in ??955, ??960, ??961, ??963, ??969, ??978, ??980 and the recent flood in Ibadan occurred in 2011.
41 The 2011 floods which occurred in Ibadan between august to October, 2011 was one of the most devastating
42 in the city. According to Erekpokeme, (2015), the flood incidence in Ibadan in the year 2011 claimed lives and
43 properties which include farmland, farmproduce, and animals (Onwuemele, 2012).

6 RESULT AND DISCUSSION

44 It is a pity that agriculture tends to suffer the most when there is a flood in Nigeria properly due to the
45 sensitivity and fragility of its natural environment as well as its high dependence on environment-based livelihoods.
46 Women farmers are not left out in this overwhelming disaster, and many of them were unable to recover up to
47 date. It is disheartening that agricultural policies on the whole still do not address the needs of women farmers
48 adequately after floods incidence in their domain. Agricultural development programs might be misinterpreted
49 in the long run if the roles and needs of women farmers are not recognized in policy. Therefore there is a need
50 to critically look at the effect of floods on women activities with the intention to I Volume XX Issue III Version
51 I encourage the policy makers to gives adequate attention to women farmers and their needs.

52 The aim of the study, therefore is to assess the effect of flood on women farmers' activities in the floodprone
53 area in Ibadan Metropolis, Oyo State, Nigeria. The study also identified the types of farming activities engaged
54 by the women as well as the relationship between the farming activities and the effect of floods in the study
55 areas.

56 2 II.

57 3 Methodology

58 The study area was Oluyole Local Government Area of Ibadan, Oyo State, Nigeria. It shares boundaries with
59 four Local Government Area, i.e. Ibadan South-West, South-East, Ona -Ara and Ido within Ibadan Metropolis,
60 and lies between latitude 7 o 25' N and longitude 3 o 5'. ??NPC, 2007). Data were collected through interviews
61 with the aid of a well-structured questionnaire and directed towards women farmers. Oluyole Local Government
62 was purposively selected for the study. This is because the area is prone to flood occurrence during the raining
63 season.

64 The sampling technique was multi-staged. Four out of the 10 wards in Oluyole Local Government were
65 purposively selected which was the first stage. In contrast, the second stage involved a random selection of the
66 villages from the wards. The wards selected were 4, 8, and 9, which contained two villages respectively, and ward
67 5 had three villages. Random selection of one village respectively from each selected wards was carried out based
68 on the history of floods destruction to farm produce on farmlands in the wards selected. The villages selected
69 across the wards are Abanla, Busogboro, Odo-Ona Elewe, and Idi Ayunre.

70 In the last stage, farmers (women) counting was carried out to obtain a population in each village using the
71 PRA technique. 20% of the population obtained was then used to select the respondents in list that ensue.
72 Below is an illustration of the sampling procedure and sample size The data were analyzed using descriptive and
73 inferential analyses. The descriptive statistics used include frequency distributions and percentages, mean, while
74 the relationship between agricultural activities and effect of the flood on women farmer's activities in the study
75 area was examined using inferential statistics such as PPMC were used to examine

76 4 a) Measurement of variable

77 A five-point scale of a "strongly agree," "agree," "uncertain," "disagree," and "strongly disagree" was used to
78 measure the effect of the flood on women farmers, which is the dependent variable. A score of 5 was assigned
79 to "strongly agree," 4 to "agree," 3 to "uncertain," 2 to "disagree," and 1 to "strongly disagree. The highest
80 score obtainable was 50, and the lowest is 10. The effects were categorized as high and low. A twopoint scale
81 of yes and No was used to measure the second variable (agricultural activities). A score of 2 was assigned to
82 yes, 1 to no. Thirteen questions were asked. Hence the highest score obtained was 26 and the lowest was 13.
83 The reasons were categorized to high, and low. The table above indicates that the majority of the respondents
84 (90.1%) engaged in poultry production. The respondent's engagement in this activity constituted the major
85 proportion of participation in agricultural activities in the study area. This implies that the respondents possess
86 a very large amount of poultry in the study area. The assertion is in aligns with Okitoil et al. ??2007), who
87 reported that women in rural areas are majorly interested in poultry production. Also, it was revealed that 84.0%
88 of the respondents were into vegetable production. The involvement of the respondents might be attributed to
89 the fact that vegetables can be grown even with little space available in the study area, thereby contributing to
90 their source of livelihood. It is in line with Nakwe et al., ??2018). They reported that the chief occupation of
91 most women living in rural areas is agriculture, and they produce most of the vegetables consumed in rural areas.
92 This table above revealed that 65.4% of the respondents in the study area also engaged in cash crop production.
93 Furthermore, it was revealed that more than half (51.9%) of the respondents were into arable crops production.
94 The involvement of the respondents in the cultivation implies that the respondents generally make good use
95 of available land that is accessible to them, especially for backyard farming and all the agricultural practices
96 mentioned above. This finding is in line with Ekesionye and Okolo (2012), who found that women were actively
97 involved in economic activities.

98 5 III.

99 6 Result and Discussion

100 Table ??: Effect of Flood on Women Farmers in the study area.

101 The result showed that 64.2% of the respondents strongly agreed that the effect of the flood on their farms
102 resulted in low nutrient in the soil. This implies that when a flood occurs, the nutrients are leached off.
103 Corroborating this, Akpoveta et al., (2014) opined that flood occurrence significantly decreased the nutrients
104 in the soil. Also, 61.7% of the respondents agreed that the flood negatively affects the yield on the farm. The
105 report could be because flood destroyed most of the farm produce, which also included the farm produce stored
106 in the storage facilities. This assertion supported the findings of Aluko et al ??2020) the incidence of water flood
107 in the study area left the farmers with little or nothing to hold on to. Furthermore, 51.9% of the respondents
108 agreed that, whenever flood occurs it affect family income, and revenue available at their disposal. The statement
109 implies that the flood issue in the study area may reduce the income earned at the end of each farming season
110 drastically. Also, 49.4% of the respondents reported that flood resulted in migration (moving from one place to
111 another) to less flood-prone areas. The affirmation, by the respondents implies that respondents migrated from
112 the flooded affected areas to non-affected flood areas for the safety of lives and properties.

113 Based on the results from the table above, flood affects ways of leaving of the people with the majority either
114 agreed or strongly agreed that it led to reduction in labor used for farming activities, loss of crops and livestock
115 on the farm, decline in the standard of living as well as the outbreak of diseases in the study area. The correlation
116 analysis on Table 5 shows that there is a significant relationship between respondents' agricultural activities and
117 the effect of the flood ($r=-0.151$, $p < 0.05$). The negative correlation suggests that the nature of farming activities
118 practiced by the respondents also contributed to the effect of flood in the study area. The statement could be
119 attributed to the fact that most of the respondents preferred lands closer to the river boundary which could have
120 a negative impact on their activities as a result of high risk to flood during the raining.

121 IV.

122 7 Conclusion

123 The study revealed that flood hurt the respondents resulting to the migration, the reduced yield of the produce,
124 reduction in quality of output, and loss of nutrients in the soil in the area. Farmers, especially women, are
125 vulnerable to flood due to warmer climate and a higher rate of evaporation, which is contributing to an increase
126 in the average annual amount of rain.

127 Despite engaging in various agricultural activities to minimize the effect on their activities and way of life, the
128 finding revealed that the level of the flood was high (61.73%) among the respondents in the study area.

129 V.

130 8 Recommendation

131 The following are recommendations made based on the findings of this study.

132 ? The government should construct drainages in flood-affected areas and diversify a means of storing up excess
133 water, to avoid the damage caused by flood yearly. ? The government should plant trees and encourage farmers
134 to plant trees that could prevent washing away from farmland. ? Farmers should be encouraged to construct
135 flood diversion channels that involve the artificial construction of channels along main river channels to divert
136 part of the discharge during flood flows.

Level	Frequency	Percentage
Low	31	38.27
High	50	61.73
Total	81	100

From the table above, the level of the flood was high (61.73) among the respondents in the study area. The assertion implies that overflow of water had severe

negativity in the farming activities of the respondents in the study area.
